Lecture 24: Comparing two population means Chapter 18

Instructor: Tomer Altman

October 24, 2025

Recap

- ➤ So far we've learned the *z*-test and the *t*-test that apply when the variable of interest is continuous
- ▶ These are **one sample** tests, meaning we have one variable of interest, and we take one sample. We're interested in knowing whether the one sample differs from some null hypothesized value ($H_0: \mu = 68mm$)

Next up: comparing two population means

In Chapter 18, we are interested in comparing two samples from two populations. We want to shed light on the question: Do these two samples have the same underlying mean, or are their means different? Another way of phrasing this is, "is the difference between the means equal to 0 or not?"

For this question, our null and two-sided alternative hypotheses are:

$$H_0: \mu_1 - \mu_2 = 0$$

$$H_A: \mu_1 - \mu_2 \neq 0$$

You can also write them this way, by rearranging the equation:

$$H_0: \mu_1 = \mu_2$$

$$H_A: \mu_1 \neq \mu_2$$

Comparing two population means

In public health, we are often most interested in questions that compare two groups (exposed vs. unexposed, treatment vs. placebo, etc.):

- Run a randomized controlled trial where we compare a treated subgroup to a placebo group. Do their mean health outcomes differ?
- Conduct an observational study where we have exposed and unexposed individuals. Do their mean health outcomes differ?

In this chapter, we talk about tests to compare the difference in two continuous means, represented by μ_1 and μ_2 .

Comparing two samples, graphically

Procedure to compare two samples graphically

- Make two histograms, one for each sample
- Compare their shapes, centers (means or medians) and spreads (standard deviations)
- Or, make two box plots and compare their medians and IQRs

Conditions for inference comparing two means

- ▶ We have two SRSs, representing two distinct populations.
 - ► The samples are **independent**. That is, the individuals in one sample are unrelated to the individuals in the other sample.
 - We measure the same quantitative variable for both samples.
- ▶ Both populations are **Normally distributed**. The means and standard deviations of the populations are unknown.
- ▶ In practice, it is enough that the distributions have:
 - similar shapes
 - sample sizes are "big enough"
 - data have no strong outliers

Notation

Notation for the population parameters:

| Population | Variable | Population mean | Population SD |
|------------|-----------------------|-----------------|---------------|
| 1 | <i>x</i> ₁ | μ_1 | σ_1 |
| 2 | <i>x</i> ₂ | μ_2 | σ_2 |

Notation

Notation for the sample statistics:

| Population | Sample size | Sample mean | Sample SD |
|------------|-------------|-------------|-----------------------|
| 1 | n_1 | \bar{x}_1 | s_1 |
| 2 | n_2 | \bar{x}_2 | <i>s</i> ₂ |

To perform inference about the difference between the means $(\mu_1 - \mu_2)$, we first estimate the difference $\bar{x}_1 - \bar{x}_2$ between the sample means.

Two-sample *t* test

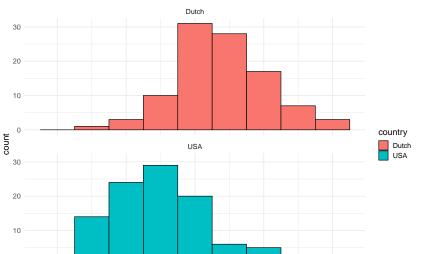

- Nith one-sample tests, we have one \bar{x} and we sketch the sampling distribution for \bar{x} . It is centered at μ with standard error $\frac{\sigma}{\sqrt{n}}$
- ▶ With two-samples, we have two sample averages \bar{x}_1 and \bar{x}_2 .
- ► What do we do?

Example with adolescent heights from two different countries

Are the heights of US and Dutch-born men different?

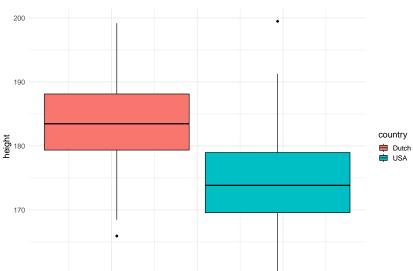

Compare the histograms

```
ggplot(height_data, aes(x = height)) +
  geom_histogram(aes(fill = country), binwidth = 5, col =
  theme_minimal(base_size = 15) +
  facet_wrap(~country, nrow = 2)
```

Compare the boxplots

```
ggplot(height_data, aes(y = height)) +
  geom_boxplot(aes(fill = country), col = "black") +
  theme_minimal(base_size = 15)
```

Example with adolescent heights from two different populations

Are the heights of US and Dutch-born men different?

$$ar{x}_{USA}=174.7042$$
 and $ar{x}_D=183.6690$ so the difference is $ar{x}_D-ar{x}_{USA}=8.9648$

What would happen if we took another set of two samples of USA and Dutch-born men? We would expect these sample means to change. We could draw an approximate **sampling distribution for the difference** between these two means.

The sampling distribution of $\bar{x}_1 - \bar{x}_2$

The distribution of the difference between two independent random variables has a mean equal to the difference of their respective means and a variance equal to the weighted sum of their respective variances. That is:

- ► The mean of the sampling distribution for $\bar{x}_1 \bar{x}_2$ is $\mu_1 \mu_2$. ► The variance of the sampling distribution is: $\frac{\sigma_1^2}{n_1} + \frac{\sigma_2^2}{n_2}$
- The standard deviation of the sampling distribution is:

$$\sqrt{\frac{\sigma_1^2}{n_1} + \frac{\sigma_2^2}{n_2}}$$

Our estimate of the standard deviation of the sampling distribution is: $SE = \sqrt{\frac{s_1^2}{n_1} + \frac{s_2^2}{n_2}}$

Recall the t-test

$$\frac{\bar{x} - \mu_0}{\frac{s}{\sqrt{n}}}$$

We need to generalize this by replacing each piece in the *t*-test by the calculations on the previous slide.

The **two-sample** *t*-test is therefore:

$$t = \frac{(\bar{x}_1 - \bar{x}_2) - (\mu_1 - \mu_2)}{SE}$$

$$t = \frac{(\bar{x}_1 - \bar{x}_2) - (\mu_1 - \mu_2)}{\sqrt{\frac{s_1^2}{n_1} + \frac{s_2^2}{n_2}}}$$

The two-sample t statistic has approximately a t-distribution. The approximation is accurate when both sample sizes are greater than or equal to 5.

The degrees of freedom (df) for the two-sample t-test. . .

is bananas. Here is the formula:

$$df = \frac{\left(\frac{s_1^2}{n_1} + \frac{s_2^2}{n_2}\right)^2}{\frac{1}{n_1 - 1} \left(\frac{s_1^2}{n_1}\right)^2 + \frac{1}{n_2 - 1} \left(\frac{s_2^2}{n_2}\right)^2}$$

Where:

- $ightharpoonup s_1^2$ is the sample variance for sample #1
- $ightharpoonup s_2^2$ is the sample variance for sample #2
- \triangleright n_1 is the sample size for sample #1
- $ightharpoonup n_2$ is the sample size for sample #2

Note, that if sample size is large enough, the test statistic will follow a N(0,1) distribution and this calculation becomes much less important.

Confidence intervals for the two-sample *t*-test

$$(\bar{x}_1 - \bar{x}_2) \pm t^* \sqrt{\frac{s_1^2}{n_1} + \frac{s_2^2}{n_2}}$$

Here t^* is the critical value with area C between $-t^*$ and t^* under the t-distribution with the appropriate degrees of freedom.

Hypothesis testing when you have two samples

$$H_0: \mu_1 - \mu_2 = 0$$

$$H_A: \mu_1 - \mu_2 \neq 0$$

Here we consider the two-sided alternative hypothesis, but you could be interested in the one-sided alternative in either direction:

$$H_A: \mu_1 - \mu_2 > 0$$

Obtain the two-sample t-test statistic

$$t = \frac{(\bar{x}_1 - \bar{x}_2) - (\mu_1 - \mu_2)}{\sqrt{\frac{s_1^2}{n_1} + \frac{s_2^2}{n_2}}}$$

Under the two-sided null hypothesis:

$$t = \frac{\left(\bar{x}_1 - \bar{x}_2\right) - 0}{\sqrt{\frac{s_1^2}{n_1} + \frac{s_2^2}{n_2}}}$$

Example, continued

##

Let R do the work for you:

```
t.test(height_data_wide %>% pull(usa),
    height_data_wide %>% pull(dutch),
    alternative = "two.sided")
```

```
## Welch Two Sample t-test
```

##

data: height_data_wide %>% pull(usa) and height_data_w:
t = -9.1103, df = 197.35, p-value < 2.2e-16</pre>

```
## alternative hypothesis: true difference in means is not
## 95 percent confidence interval:
## -10.905418 -7.024282
```

sample estimates:
mean of x mean of y
174.7042 183.6690

Note that t.test gives you both the *t*-test results (including the

Example 2: Transgenic chickens

Infection of chickens with the avian flu is a threat to both poultry production and human health. A research team created transgenic chickens resistant to avian flu infection. Could the modification affect the chicken in other ways? The researchers compared the hatching weights (in grams) of 45 transgenic chickens and 54

```
independently selected commercial chickens of the same breed.

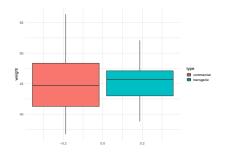

transgenic <- c(38.8, 39.0, 39.7, 40.0, 40.8, 40.9, 41.0, 40.0, 43.0, 43.4, 43.5, 43.5, 43.8, 44.4, 44.7, 40.0, 40.8, 40.9, 41.1, 40.5, 40.6, 40.7, 40.7, 40.8, 40.9, 40.7, 40.8, 40.9, 40.7, 40.8, 40.9, 40.8, 40.3, 40.3, 40.3, 40.3, 40.3, 40.3, 40.3, 40.3, 40.3, 40.3, 40.3, 40.3, 40.3, 40.3, 40.3, 40.3, 40.3, 40.3, 40.3, 40.3, 40.3, 40.3, 40.3, 40.3, 40.3, 40.3, 40.3, 40.3, 40.3, 40.3, 40.3, 40.3, 40.3, 40.3, 40.3, 40.3, 40.3, 40.3, 40.3, 40.3, 40.3, 40.3, 40.3, 40.3, 40.3, 40.3, 40.3, 40.3, 40.3, 40.3, 40.3, 40.3, 40.3, 40.3, 40.3, 40.3, 40.3, 40.3, 40.3, 40.3, 40.3, 40.3, 40.3, 40.3, 40.3, 40.3, 40.3, 40.3, 40.3, 40.3, 40.3, 40.3, 40.3, 40.3, 40.3, 40.3, 40.3, 40.3, 40.3, 40.3, 40.3, 40.3, 40.3, 40.3, 40.3, 40.3, 40.3, 40.3, 40.3, 40.3, 40.3, 40.3, 40.3, 40.3, 40.3, 40.3, 40.3, 40.3, 40.3, 40.3, 40.3, 40.3, 40.3, 40.3, 40.3, 40.3, 40.3, 40.3, 40.3, 40.3, 40.3, 40.3, 40.3, 40.3, 40.3, 40.3, 40.3, 40.3, 40.3, 40.3, 40.3, 40.3, 40.3, 40.3, 40.3, 40.3, 40.3, 40.3, 40.3, 40.3, 40.3, 40.3, 40.3, 40.3, 40.3, 40.3, 40.3, 40.3, 40.3, 40.3, 40.3, 40.3, 40.3, 40.3, 40.3, 40.3, 40.3, 40.3, 40.3, 40.3, 40.3, 40.3, 40.3, 40.3, 40.3, 40.3, 40.3, 40.3, 40.3, 40.3, 40.3, 40.3, 40.3, 40.3, 40.3, 40.3, 40.3, 40.3, 40.3, 40.3, 40.3, 40.3, 40.3, 40.3, 40.3, 40.3, 40.3, 40.3, 40.3, 40.3, 40.3, 40.3, 40.3, 40.3, 40.3, 40.3, 40.3, 40.3, 40.3, 40.3, 40.3, 40.3, 40.3, 40.3, 40.3, 40.3, 40.3, 40.3, 40.3, 40.3, 40.3, 40.3, 40.3, 40.3, 40.3, 40.3, 40.3, 40.3, 40.3, 40.3, 40.3, 40.3, 40.3, 40.3, 40.3, 40.3, 40.3, 40.3, 40.3, 40.3, 40.3, 40.3, 40.3, 40.3, 40.3, 40.3, 40.3, 40.3, 40.3, 40.3, 40.3, 40.3, 40.3, 40.3, 40.3, 40.3, 40.3, 40.3, 40.3, 40.3, 40.3, 40.3, 40.3, 40.3, 40.3, 40.3, 40.3, 40.3, 40.3, 40.3, 40.3, 40.3, 40.3, 40.3, 40.3, 40.3, 40.3, 40.3, 40.3, 40.3, 40.3, 40.3, 40.3, 40.3, 40.3, 40.3, 40.3, 40.3, 40.3, 40.3, 40.3, 40.3, 40.3, 40.3, 40.3, 40.3, 40.3, 40.3, 40.3, 40.3, 40.3, 40.3, 40.3, 40.3, 40.3, 40.3, 40.3, 40.3, 40.3, 40.3, 40.3, 40.3, 40.3, 40.3, 40.3, 40.3,
```

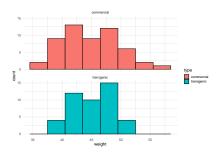

50.4, 50.6, 52.2, 53.0, 55.5, 56.4)

chicken data <- data.frame(weight = c(transgenic, commercial)

47.3, 47.5, 48.1, 48.2, 48.4, 48.6, 49.0,

Example 2: Transgenic chickens

Estimate the size of the difference between the two means

```
means <- chicken_data %>%
 group_by(type) %>%
 summarise(mean_weight = mean(weight))
means
## # A tibble: 2 x 2
## type mean weight
## <chr> <dbl>
## 1 commercial 45.0
## 2 transgenic 45.1
diff_means <- means[1, 2] - means[2, 2]
diff means
##
    mean weight
## 1 -0.1533333
```

The estimated mean difference is -0.153 grams.

Estimate the standard error

```
SE = \sqrt{\frac{s_1^2}{n_1} + \frac{s_2^2}{n_2}} chicken_stats <- chicken_data %>% group_by(type) %>% summarise(mean_weight = mean(weight), sd_weight = sd(weight), n = length(weight))
```

Use the output to calculate the SE:

$$SE = \sqrt{\frac{4.568872^2}{54} + \frac{3.320836^2}{45}} = 0.7947528$$

Calculate the *t*-statistic

$$t = \frac{(\bar{x}_1 - \bar{x}_2) - (\mu_1 - \mu_2)}{\sqrt{\frac{s_1^2}{n_1} + \frac{s_2^2}{n_2}}}$$
$$t = \frac{(44.98889 - 45.14222) - (0)}{0.7947528} = -0.1929279$$

What is the chance of observing the t-statistic -0.193 on the t-distribution with the appropriate degrees of freedom?

- To answer this, we would need to calculate the degrees of freedom using the complicated formula from a previous slide
- We won't do this by hand
- Instead, we will ask R to do the test for us
 - ▶ and verify that our calculated *t*-statistic matches R's test

t.test in R

Pay attention to the arguments specified by t.test. Below, the first argument is the weight data for the commercial chickens and

the second argument is the weight data for the transgenic

```
chickens.
  filter(type == "transgenic")"
```

t.test(commercial_weight, trangle) alternative = "two.side ## ## Welch Two Sample t-test

data: commercial_weight ar

commercial_weight <- chicken_data %>% = -0.19293, df = 95.344, filter(type == "commercial") ## alternative hypothesis: true transgenic_weight <- chicken_data ## 95 percent confidence inter % pull(weight)
sample estimates:

> ## mean of x mean of y ## 44.98889 45.14222 What happens if you flip the order? If you flip the order, the

> > test statistic flips signs (from nogative to nocitive

Robustness of the two-sample *t*-test

- Nhen the sizes of the two samples are equal and the two populations being compared have similar shapes, the two-sample t-test will work well for sample sizes as small as $n_1 = n_2 = 5$
- When the two populations have different shapes, larger samples are needed (e.g., one skewed left and the other skewed right)
 - ► This is because the difference of averages (the estimator) becomes Normally distributed even if the underlying random variable in both groups is not Normal
